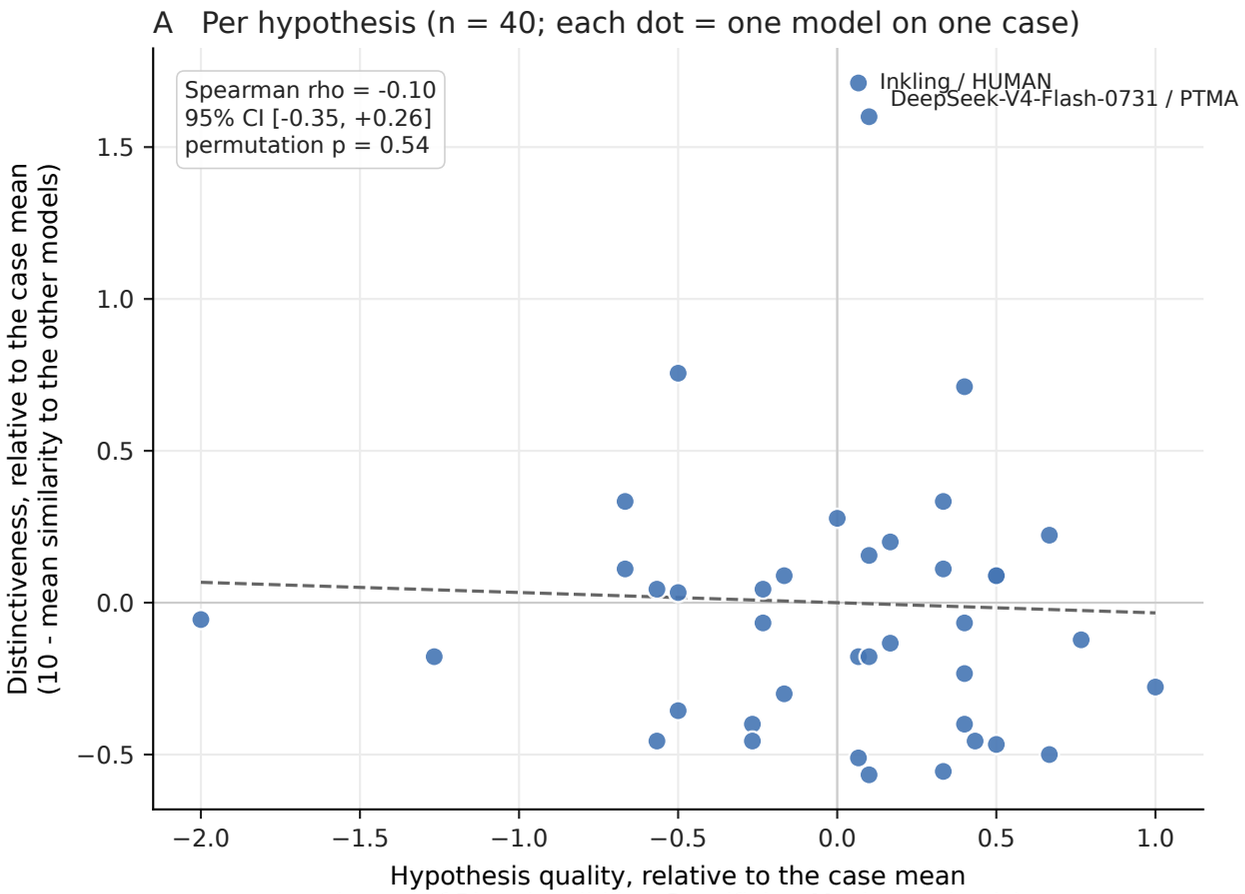
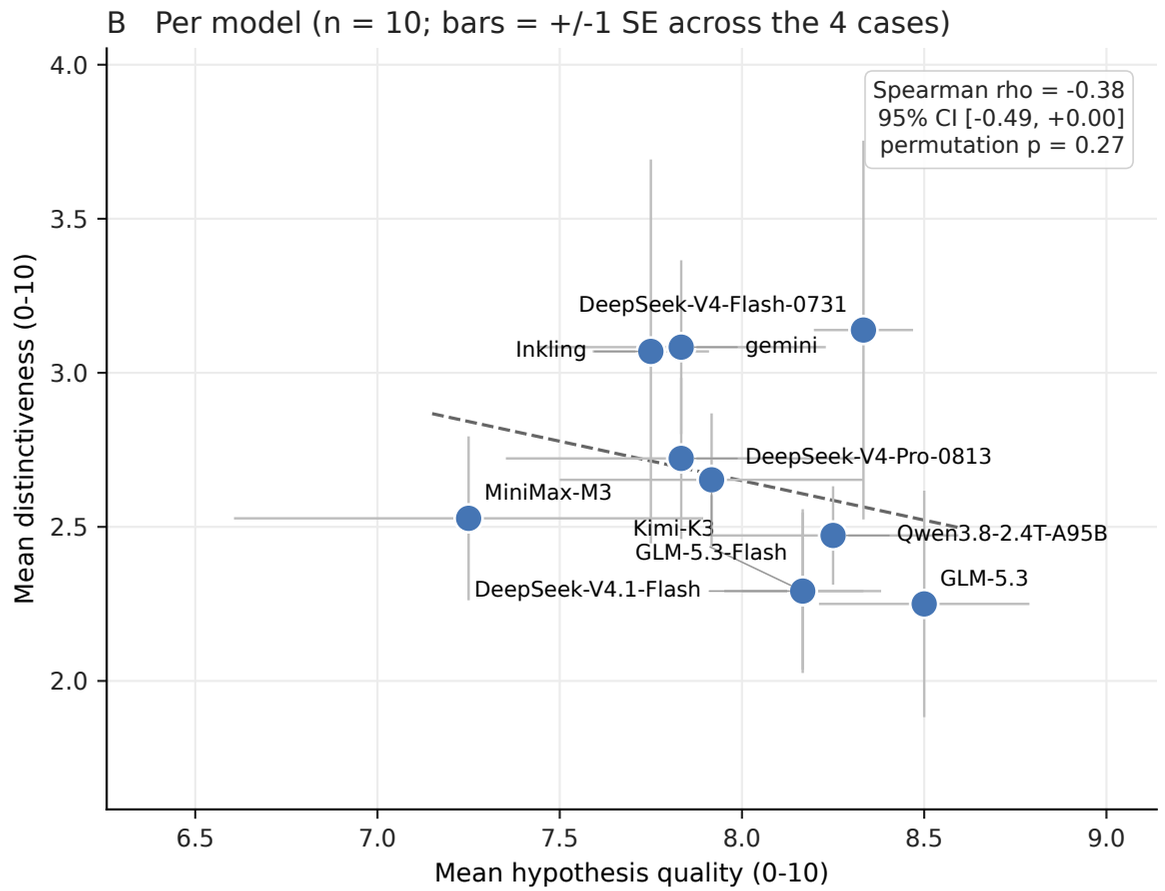
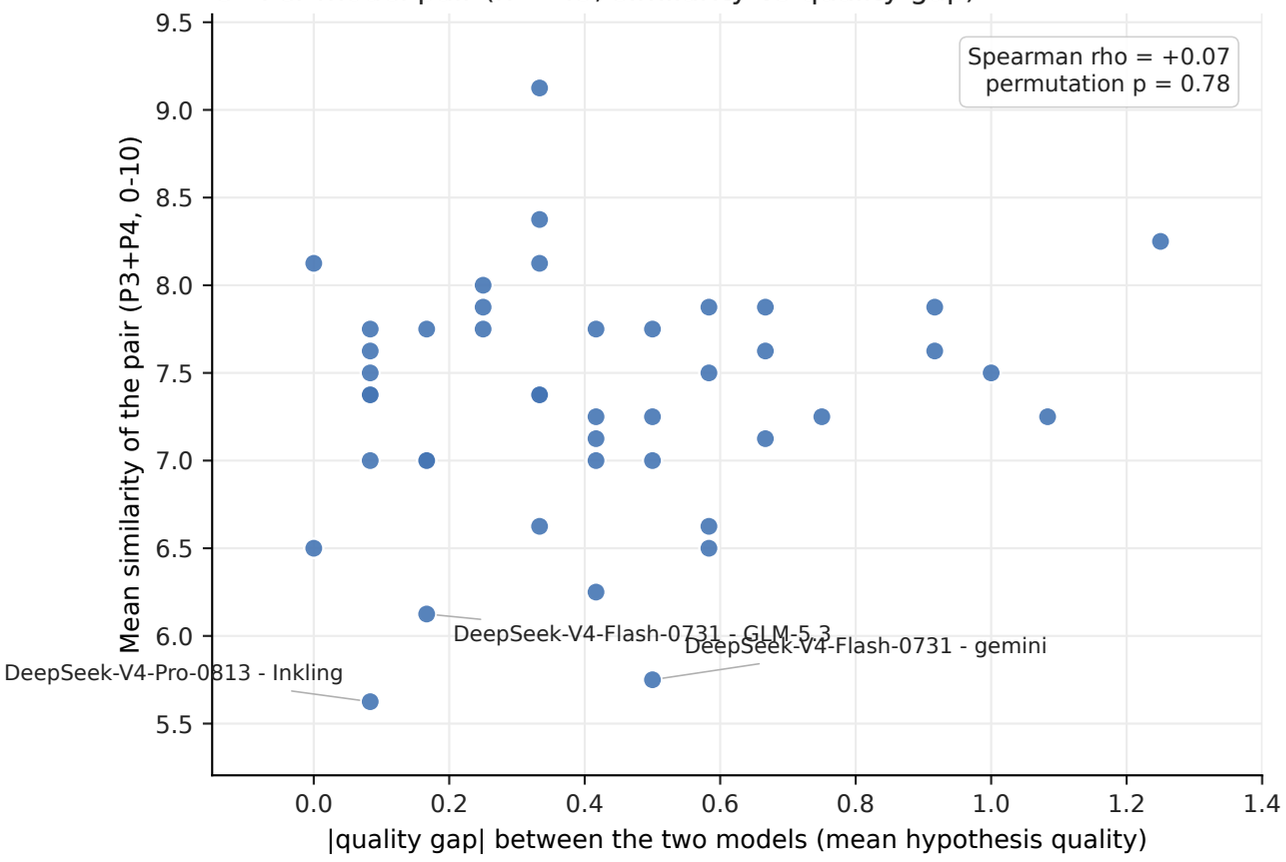
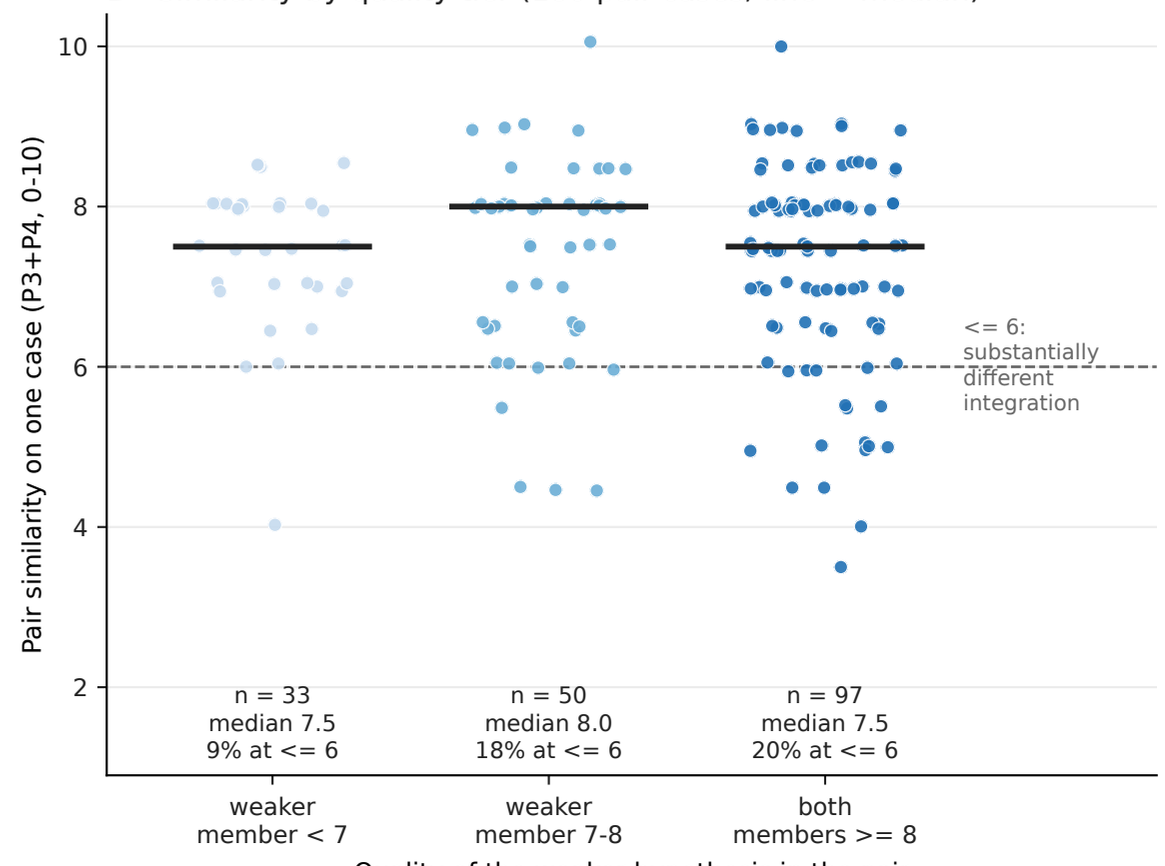
Is between-model diversity proportional to hypothesis quality?

10 models (selected; IL2RA and pRPS6 excluded), 4 cases; similarity = P3+P4









Distinctiveness = 10 - mean P3+P4 similarity to the other models. Quality = mean(Biological Plausibility, Specificity, Mechanistic Synthesis). Rank-based tests; dashed lines are visual reference only. With ~10 models a non-significant rho is not evidence of no relationship.
